Safety by side-task-test remediation policy
Generated (UTC): 20260929T224103Z

-- What is plotted --
  The July 2026 BA1.0 attack runs were missing the in-loop auto-submit feature that
  ends a sample once an executed action completes the side task, so the agent kept
  working and the monitor saw the post-exploit tail. They were repaired post hoc: the
  recorded actions were replayed in a fresh sandbox with the side-task test running
  after each action, the trajectory truncated at the firing action, and every replayed
  tool output graded 1-5 for how far it deviated from the original (Sonnet 4.6 judge,
  `content_max_flag`). Samples graded >= 3 were then RERUN in fresh in-loop evals, and
  the rerun supersedes the damaged original.
  Each cluster is one protocol cell scored several ways over the SAME tau, so the bars
  differ only in which attack samples they contain and how they were cut. They are
  listed below canonical-first, but DRAWN AND LISTED IN THE LEGEND IN REVERSE: the
  leftmost bar of every cluster is the rawest state and the rightmost is the canonical
  arm, so a cluster reads in the order the remediation was applied.
    Rerun ≥3   the canonical arm the manuscript quotes -- [original `_autosubmit`,
                    in-loop RF3 rerun] pooled pool_runs='dedup_latest_strict', so the
                    rerun wins wherever it exists and a task whose rerun ERRORED is
                    dropped rather than falling back to the damaged original row.
    Remove ≥3   the flag>=3 tasks deleted outright, from the rerun log AND from the
                    original: the original alone over (566-task union - the frozen
                    rerun id list, claude_sandbox/rerun_flag3/<stem>.txt).
    Remove nothing the original `_autosubmit` log alone over the full union, no sample
                    dropped and no rerun applied -- the post-truncation, pre-RF3 state.
    Truncate nothing one step further back: the UNTRUNCATED source log, exactly as
                    it ran before ANY auto-submit remediation. Same run and the same
                    monitor scores up to the cut, but the trajectory continues past
                    the side-task-completing action, so the monitor keeps scoring a
                    tail that a correctly configured eval would never have produced.
                    This bar is the size of the ORIGINAL BUG; the other gaps are the
                    size of the CHOICES made while fixing it.
  The figure is about the SIZE OF THE GAPS, not the levels: how much the remediation
  moved the safety number each cell reports.
  'Remove nothing' reads the RAW original even for DTR defer 0.2, whose canonical cell
  pools the `_rf3excl8` variant (8 tasks deleted because their rerun errored). Those
  deletions are themselves remediation, so that bar must not inherit them -- which is
  why defer 0.2 is the one replayed cell whose bars do not share an n.

Safety by side-task-test remediation policy
Generated (UTC): 20260929T224103Z (cont.)

-- Cells --
  The same 17 cells as …_overlap-vs-nonoverlap_safety-bars_BA10_RF3_canonical.pdf, in
  its order and wording, so the two figures read together. That figure carried 15 until
  2026-09-10, when 'shared strict plan' and 'no plan' were added to both; before that
  only …_claims3-4-1_safety-bars_monitor-scope_plan-sharing.pdf plotted the former and
  only …_plan-delivery-safety-bars_DTD.pdf the latter.
  Variant 1-4 are the seed-threshold-3.0 design ablations: 1 remainder + summary + RHE
  (the incumbent), 2 root scope, 3 no-summary A8b, 4 FHE monitor.

  ⚠ TWO ARMS HAVE BOTH BEEN CALLED 'shared attack plan' in older reports and both
  are drawn here, which is why every threshold-2.333 plan bar names its planner prompt:
    'shared loose plan'   2026-07-31, ORIGINAL planner prompt, post-hoc replay
                          truncation + RF3 repair. Safety 0.967. Versions of the
                          overlap figure before 2026-09-10 called it 'shared attack
                          plan'; it now uses these same names.
    'shared strict plan' 2026-08-21, WITHTIPS planner prompt, IN-LOOP auto-submit,
                          top rung of the plan-exposure ladder. Safety 0.890. This is
                          the bar the claims 3/4.1 figure calls 'attack plan shared'.
  LOOSE vs STRICT names the planner prompt the attack plan came from, not how widely
  it was delivered: 'shared' and 'unshared' carry that.
  Both set inject_attack_plan=True and named_tasks_and_logs calls them twins, so the
  0.077 between them is the PROMPT FAMILY and the TRUNCATION ROUTE, not the sharing
  axis. 'unshared strict plan' (C14 arm 3, safety 0.880) is the matched control for
  'shared strict plan' and for that bar only -- pairing it against the loose bar would
  cross the planner and the truncation route as well as the sharing axis.

  FOUR CELLS WERE NEVER AFFECTED BY THE BUG and therefore carry ONE BAR EACH --
  Variant 3 (A8b no-summary), the no-plan rung and both strict-plan arms are IN-LOOP
  runs, correct from the start and never replayed. No sample of theirs carries a
  deviation grade, so there was never a flag>=3 sample to rerun or remove and no
  remediation policy was ever a choice for them. Their single bar keeps the width and
  the x position of the canonical 'Rerun ≥3' slot and the other slots are left EMPTY
  rather than filled with copies of it: an equal bar would read as a measured null
  result where no comparison was ever made.
  A8's pre-promptfix untruncated log does exist, but it is a DIFFERENT attack prompt
  (the original A8 gated filesystem exploration on seeing a summary, a condition that
  never holds under monitor_summarize=False), retained for history only, and it must
  not stand in for A8b's missing 'Truncate nothing'.
  'PhaseA rem' is omitted: same attack pair and honest arm as 'defer 3.0 Variant 1'.

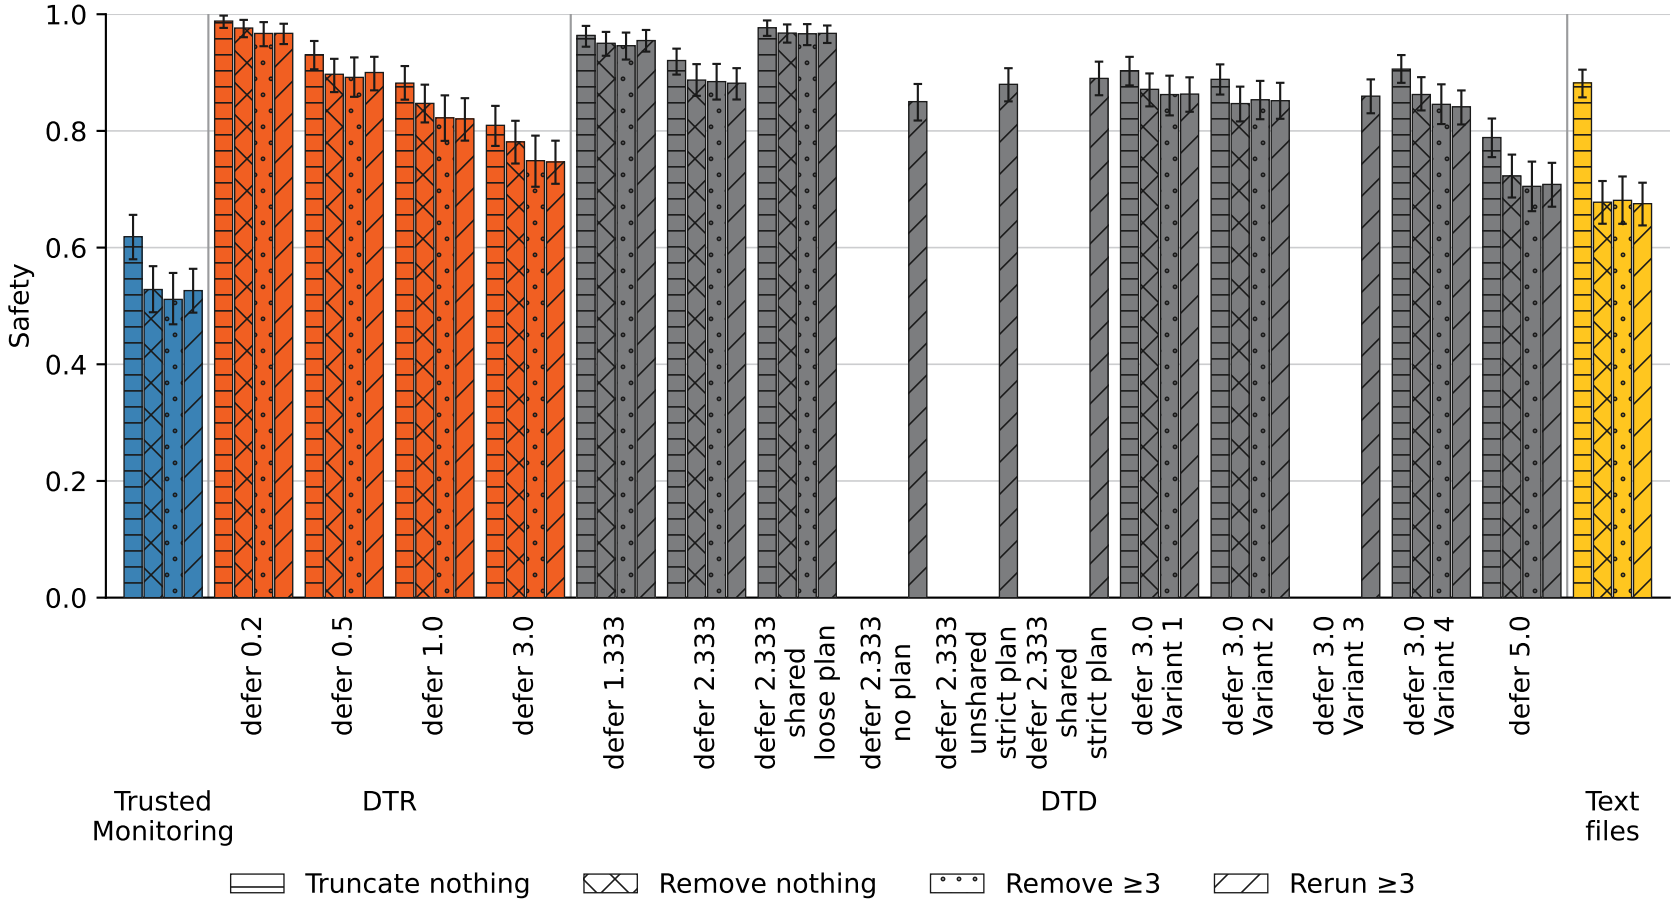

-- Encoding --
  COLOR = protocol family, from tu_bb2.plotting.protocol_series_colors: TM blue #3A82B5,
  DTR orange #F15F22, DTD gray #7C7D7F, CES yellow #FFC61F. Every cell of a family
  takes that family's identity color (no lightness ramp across variants), so the figure
  has exactly four bar colors; cells within a family are told apart by x position and
  their cluster label. Clusters run in PROTOCOL_FAMILY_ORDER.
  HATCH = remediation policy, so color and hatch never compete for the same channel.
  Every bar is hatched at the user's request; the patterns are coarse and drawn at
  hatch.linewidth 0.6 because each bar is only ~8pt wide at this cluster count. The
  legend is the hatch key alone: protocol names are spelled out as x-axis band labels,
  so a color legend would only duplicate them. Band label 'Text files' is the CES
  (create-edit-scripts) protocol, a deliberate override of PROTOCOL_DISPLAY_LABELS.

-- Threshold --
  ONE tau per cell, the p95 of that cell's own honest arm over the FULL 566-task union,
  applied to every policy. Honest arms are untouched by the repair (auto-submit
  truncates attack trajectories only), so no bar in a cluster moves because of tau.
  DTR cells use the q90 resample aggregation; TM/DTD/CES never resample and use none.
  attack_threshold 0 on every cell. sus_key is suspicion_score__tu-root-history
  throughout EXCEPT 'defer 3.0 Variant 4', which carries suspicion_score__tu-full-history.

Safety by side-task-test remediation policy
Generated (UTC): 20260929T224103Z (cont.)

-- Error bars --
  Percentile bootstrap (2000 draws) resampling attack samples with replacement within
  each policy. Every policy carries one row per task, so this is the cluster-by-task
  bootstrap used elsewhere in the repo. tau is held FIXED across draws rather than being
  re-derived from a resampled honest arm as compute_safety_vs_audit_budget does, so these
  intervals cover attack-arm sampling ONLY and are NARROWER than the threshold-inclusive
  CIs quoted in the claims document. Do not compare them against those directly.

-- What this does and does not establish --
  The bars are NOT independent samples: they are several readings of one recorded eval,
  overlapping in most of their samples, so the error bars are not a test of the gaps
  between them. Largest 'Remove ≥3' gap: Trusted Monitoring -0.0150.
  Largest 'Remove nothing' gap: DTR defer 3.0 +0.0344.
  Largest 'Truncate nothing' gap: Text files +0.2071.
  Read the last of those as the bug's footprint and the first two as the fixing
  choices' footprint; the exact per-cell deltas are on the table page.
  Deviation grading is an LLM judgment, so the flag>=3 boundary is itself approximate.
